Abstract Family firms are the most prevalent type of firm in the world and account for a large proportion of the economic activity and employment, especially in developing countries. We consider firms to be “family controlled” when the founding family owns over 25% of shares and the CEO is a family member. In this paper we investigate the relationship between family control and firm organization and performance in the manufacturing sector of primarily emerging economies. To do this we collect a new detailed dataset of the succession history in terms of ownership (who owns the shares) as well as control (who is the CEO) for over 800 firms in Latin America, and Southern Europe. We merge this with a unique dataset on firm performance and organizational structures, including on quality of managerial practices. We exploit exogenous variation in the composition of the family CEO’s children, and use it as an instrumental variable for family ownership *and* control. Our results suggest that family-owned-and-controlled firms are worse managed, with coefficients being over twice larger under 2SLS than OLS. In general the negative link seems to stem from the family vs non-family *control* rather than simply family or non-family *ownership*. Firms owned by families but with non-family CEOs do not suffer from the deficit in management quality.¹

¹We would like to thank CAF for their generous funding that started this research project, Santander Travel Awards and Nuffield College for the funding that allowed us to spend time at IBGE in Brazil, and PEDL, The IGC, the World Bank and the IADB for the funding that allowed us to collect World Management Survey data for Africa and Latin America. We also thank Carlos Lessa along with the IBGE staff for access to the Brazilian Industrial Census (PIA). We are indebted to Steve Bond, Serguey Braguinsky, Rachel Cassidy, Nicholas Chesterley, Pascaline Dupas, Dave Donaldson, James Fenske, Michael Keane, Michael Koelle, Julien Labonne, Simon Quinn, Christopher Roth, Kalina Manova, Margaret Stevens and seminar audiences in Oxford, Stanford, IZA @ DC, UNSW, Stanford Empirical Management Conference, CSAE Conference, RES Conference, RES Junior Symposium, Barcelona GSE Summer Forum, CCC at Bocconi and PacDev-Riverside for very helpful comments and discussions. We particularly thank Nick Bloom, Raffaella Sadun and John Van Reenen for their support over the years.

1 Introduction

What drives firm productivity and growth has long been a fundamental question in economics. Although there are myriad factors that contribute to the wide dispersion of firm performance across countries, the structure of ownership and control of firms, particularly “dynastic” family control, seems to be important across both developed and developing countries. But why are family firms worse performers than non-family firms on average? We take the first look at the relationship between firm governance structures (more specifically, family CEOs in family firms) and firm management and performance in a sample of medium and large firms in the manufacturing sector in primarily emerging economies in Latin America and countries in Southern Europe. We propose that one of the mechanisms that may be behind family firms’ underperformance is poor managerial practices. To consider this, we create a new survey tool to capture full firm ownership and control succession information along with family characteristics of the family behind the family firm. We merge this data with external datasets of firm performance and management and use an instrumental variables approach exploiting exogenous variation in family structure to support a causal interpretation of our results.

We consider to be “family firms” those firms that have the founding family as the controlling shareholder block *and* a family member as the CEO: the most common type of governance structure in the world.² Although several studies have looked at the relationship between family ownership and firm performance, they have mainly focused on developed countries, where the share of family firms is substantial but not as ample as in developing countries, and the studies have offered only partial evidence of channels underlying this phenomenon.³ One limiting factor in studying this type of question is lack of data availability for linked ownership and control structures and firm performance data. One notable exception is [Bennedsen et al. \(2007\)](#), where the authors use rich census data to carry out a rigorous study of the relationship between family succession and firm productivity in Denmark. Such data is, however, notoriously scarce and generally only available from the Scandinavian nations.

²[La Porta et al. \(1999\)](#) have looked at the largest firms across the richest countries in the world and found this result, though they looked only at the largest firms and across several sectors. Our focus here is medium-sized firms in the manufacturing sector.

³For example, see [Bennedsen et al. \(2007\)](#), [Bertrand & Schoar \(2003\)](#), [Claessens & Djankov \(1999\)](#), [Mueler & Philippon \(2011\)](#), [Bandiera et al. \(2012\)](#).

In the context of this literature, a succession in ownership occurs when the controlling shareholder block changes, such as when a founding family sells shares of their firm such that another entity owns more than 25% of the voting shares. A succession in control, however, happens when the CEO changes regardless of changes in ownership.⁴ Our data includes detailed information on the full history of successions of ownership *and* control. This allows us to tease out the individual effect of family control by exploiting the gender of the previous family CEO's children as a source of variation in family CEO successions that is, conditional on observables, plausibly exogenous to firm performance and management. [Bennedsen et al. \(2007\)](#) used a similar IV strategy to explore the effect of family control on traditional firm performance measures such as sales and profits, and the authors found strong negative results. Given the lack of such reliable traditional outputs data at the firm level for a number of the emerging economies we are studying, we primarily use a measure of the internal organizational structure of the firm as an outcome (management practices), rather than conventional measures of firm output such as sales or profits. Further, management is an interesting outcome in itself and we propose that it could be one of the channels explaining the lower performance outcomes of family firms. Our results are broadly consistent with [Bennedsen et al. \(2007\)](#) in that we find that a family succession leads to negative firm outcomes.⁵

Our results are the following: first, we find that indeed manufacturing firms with family owners and family CEOs have significantly worse performance as well as worse management practices. This expands on the findings from [Bloom & Van Reenen \(2007, 2010\)](#) by presenting the first results suggesting a causal link. Our IV results suggest the causal relationship between a succession to family control and management practices is decidedly negative, and estimate the magnitude of the effect, in standard deviations, to be -0.808 using 2SLS compared to -0.369 from an OLS estimation. We test the strength of this result using several alternative specifications and find it to be robust. Second, contextualizing these results, we present new evidence of the relationship between management practices and firm performance for a sample of family firms in a large emerging economy: Brazil. Our results suggest that a one standard deviation increase in the quality of management

⁴The changes may, of course, happen at the same time as well as separately.

⁵The relationship between management and productivity is a parallel research agenda started by Nick Bloom and John Van Reenen. Our focus here is more specific in looking at the relationship between management and firm outcomes in emerging economies and family firms, as well as potential channels of this relationship for this subset of firms.

practices is correlated with 15% higher sales per employee and 20% higher value added per employee in Brazilian family firms. Third, we find that within the countries we study, it is the existence of *at least one* son that matters more for family firm succession rather than simply the gender of the eldest child. Fourth, despite the relatively low relevance of the gender of the eldest child, there is a strong tendency for the first male child to be the CEO’s successor, and in the absence of a son, other male family members are still chosen over daughters.

This study contributes to three different strands of literature. First, we contribute to the studies on the importance of family firms in the global economy in terms of the share of economic activity they command. [La Porta et al. \(1997, 1999\)](#) look at the largest firms in the world’s richest economies and show that family firms are the most common governance type across several sectors. In Europe, [Faccio & Lang \(2002\)](#) and [Iacovone et al. \(2015\)](#) find similar results looking at public and private firms. In the US, [Anderson & Reeb \(2003\)](#) look at firms in the S&P 500 and also find that family ownership is “both prevalent and substantial.” In Asia, [Claessens et al. \(2000\)](#) find that more than two-thirds of firms have a single controlling shareholder, and that much of the corporate wealth belongs to a small number of families. [Cai et al. \(2013\)](#) find similar trends in Chinese private firms. Among the large number of studies looking at the ubiquity of family firms, most look at OECD and large Asian economies, and generally focus on large (and often public) firms. Few studies focus on Latin America and Africa, and when they do, it is often with a focus on microenterprises.⁶

Although small firms account for the vast majority of firms in these countries, medium-sized firms account for a much larger share of employment in Latin America and Africa. Figure 1 shows the proportion of family firms in the World Management Survey, one of our primary datasets. Two key observations emerging from this graph are: (i) developing countries have a much higher share of family firms; (ii) when looking at firms with over 50 employees — or, medium and large firms — the firm size distribution is not particularly different across countries, as evidenced by the similar circle sizes representing median firm size. Thus, in this paper we add to the literature by focussing on this important group of medium-sized firms. Firms with more than 50 employees in manufacturing account for

⁶There is a large literature looking at microfinance and microentrepreneurs, and family pressures on income sharing. As our paper focuses on medium and large firms, we do not review this literature here. For a recent study on management in small firms, see [McKenzie & Woodruff \(2015\)](#).

66% of employment in Argentina, 67% of employment in Brazil and Mexico.⁷ There are a series of studies considering the possible reasons behind this trend, which goes against the predictions found in the seminal work of Berle & Means (1932). Trust (Chami (2001)), capital imperfections of the market (Bhattacharya & Ravikumar (1997, 2001)), and legal institutions (Burkart & Panunzi (2006), Mueler & Philippon (2011)) are all expected to influence a founder’s succession decision.

[Figure 1 here]

Another strand of the literature considers the effect of ownership concentration on firm outcomes, offering mixed evidence. For example, Morck et al. (1988) finds an inverse u-shaped relationship in the US, Claessens & Djankov (1999) find a positive relationship for the Czech Republic and Demsetz & Villalonga (2001) find no relationship between ownership concentration and performance. Looking at the effect of firm CEOs on firm performance, Bertrand & Schoar (2003) provide evidence that CEO “style” matters. When considering specifically *family CEOs*, the evidence mostly points to a negative relationship, with few exceptions finding a positive relationship.⁸ The evidence of a negative relationship at the firm-level spans North America, Asia and Europe,⁹ and extends to the macro level considering the effect of large shares of family controlled firms on economic growth.¹⁰ Although these studies have taken the first step of mapping the field and describing the correlational relationship between family CEOs and firm performance across several countries, analyses with cross-sectional data are generally subject to endogeneity issues. However, studies such as Bennedsen et al. (2007) have also provided causal evidence that firms led by family CEOs are, indeed, on average less productive. Our aim in this project is to add to this growing literature on mapping the degree of underperformance of family firms and eventually provide causal evidence of these effects beyond OECD countries and focus on emerging economies, where family controlled firms command a much larger share of the economy.

But why are family controlled firms worse performers than non-family controlled firms? We explore whether poor management practices could be one of the channels leading to poor performance. In general, the literature on management and productivity finds that

⁷Authors’ calculations based on 2005 firm registers for Argentina and 2010 firm registers for Brazil and Mexico.

⁸For example, Anderson & Reeb (2003), Khanna & Palepu (2000), Sraer & Thesmar (2007).

⁹For example, Morck et al. (2000), Perez-Gonzales (2006), Claessens et al. (2002), Bertrand et al. (2008), Cai et al. (2013). See Bertrand & Schoar (2006) for a good review.

¹⁰For example, Morck et al. (2005), Caselli & Gennaioli (2013).

large variations in quality of management practices across firms and countries are strongly associated with differences in performance and also finds that there are large systematic differences in the quality of management across ownership structures (Ichniowski et al. (1997), Black & Lynch (2001), Bertrand & Schoar (2003), Bloom & Van Reenen (2007, 2010), Bloom et al. (2013), Bandiera et al. (2012), Giorcelli (2016)).¹¹ Most recently, Bloom et al. (2014) show that ownership and control structures are a factor linked to the variation of management across firms and ultimately linked to firm productivity. The authors present stylized facts for over 10,000 firms in 35 countries showing that firms owned and controlled by families tend to have significantly worse management than firms under other governance structures. Using the same dataset, we show in Figure 2 the distribution of management quality for family owned-and-controlled firms, family owned but professionally controlled firms and all other firms. It is clear that the choice of CEO is an important determinant of management quality, and we return to this Figure in the empirical section.¹² If we look at management as a technology as in Alexopoulos & Tombe (2012) and Bloom, Sadun & Van Reenen (2015), this work also speaks to the literature on barriers to technology adoption in manufacturing firms (see, for example, Bloom et al. (2013), Atkin et al. (2015) and Gibbons & Roberts (2013)).

[Figure 2 here]

2 Data

2.1 Ownership and Control History data: The Ownership Survey

To study the questions we set out in this paper, we designed and implemented a new survey to collect data on the full ownership and control history of successions the firm has had since its inception. For those firms that were founded by a single founder or founding family, we also collect information on their family characteristics.¹³ We based the choice

¹¹Hereafter we will use management and management practices interchangeably.

¹²The Kolmogorov-Smirnov test of equality of distributions suggests that the distribution of firms that are non-family owned and controlled is not statistically different from the distribution of firms owned by families but controlled by a professional CEO. The test also suggests that both distributions are statistically different from the distribution of firms owned and controlled by family members.

¹³We are aware of existing M&A databases, such as Zephyr and SDC Platinum, but these collect data on changes in *ownership* rather than changes in control. Fons-Rosen et al. (2008) have created an excellent combined panel dataset using Zephyr data, and Bena et al. (n.d.) also developed an algorithm to create

of basic classification of ownership and control on other firm surveys such as the World Management Survey and the Executive Time Use survey but expanded to include more detailed data.

In 2013, we were able to survey a sample of firms within the World Management Survey dataset and document the ownership history and family characteristics of 2,176 firms (3,027 succession data points) across 12 countries in Latin America and Africa, plus Turkey. In 2014, we added a selected set of questions to the 2014 wave of the World Management Survey to collect information on the latest succession of power in the random sample of firms interviewed across Europe and Asia. In all, we have 2,755 firms (3,606 successions) in our full sample of the Ownership Survey. The sample we use, however, is based on there being at least one *change in CEO* (or, succession of control) and also for which we have enough family history data (that is, data on our instrumental variables). Further, we can only use successions that have at least one matching data point in the World Management Survey (WMS) dataset. All considered, our final dataset has 818 successions from 810 firms. In the empirical analysis section we show the relationship between the ownership categories and management for the full sample and progressively smaller samples to show that the 810 firms included in the analysis are not likely to be a highly selected sample. We also build sampling weights to account for such issues and the results are similar.

During the survey, the interviewees are asked to describe who ultimately owns the firm, and the interviewer is instructed to probe enough to find out who the single largest shareholding is and whether they own more than 25% of the controlling shares.¹⁴ Table A1 in the Appendix gives an overview of the ownership categories. In short, if the founder or the descendants of the founder own the firm and a family member is the CEO, we classify the

a Pyramid Ownership Structures dataset. Beyond the Scandinavian matched census datasets, however, there are no datasets that we are aware of that collect data on successions of *control* (rather than simply ownership), and include family characteristics of CEOs.

¹⁴Our survey is specifically concerned with *controlling shares of ownership*, similar to how Bureau van Dijk’s datasets are compiled. Thus, by more than 25% of the controlling shares we mean more than 25% of the “voting shares” or equivalent terminology. We exclude government firms from our analysis. The interviewees for the Ownership Survey are one of the following: firm CEO or executive assistant to the CEO, head of administration, or if the firm was recently sold, the longest tenured employee at the managerial level. For the WMS, the interviewees are usually the plant manager. In 2011 the WMS team conducted a follow-up project that looked to cross-check the survey information with external data sources, such as Bureau van Dijk’s data, online research through company documents and websites and call-backs. The share of correct information was very high. More specifically, the countries included in this paper had the correct ownership structure data from the survey over 75% of the time.

firm under “family control”.¹⁵ If the shares of the firm are owned by one or many individuals and the CEO is not related to them, we call the CEO a professional CEO and classify the firm under “non-family control.” If a firm is owned by a family but has a professional CEO, so we also classify them under the “non-family control.” For ease of exposition, we will henceforth refer to firms with combined family ownership and control as *family firms* and all other firms as *non-family firms*.

The variables we are collecting include a full history of ownership and control from the time of foundation and dates of these changes. For firms that at the time of inception were family firms, we ask whether the founder had children. If yes, then we ask for the gender of the first child, how many children the founder-CEO had in total and the gender of all the children. For each succession we also ask who the control was transferred to, in terms of family relationship. With this information we can ascertain whether the founder had children at all, whether the first child was male, the ratio of male to female children, and who control of the firm was passed on to within the family.¹⁶ We give further details and an example of the dataset created in the Appendix of this paper (Section A).

2.2 Organizational data: the World Management Survey

In 2013, under the umbrella of the World Management Survey (WMS) and with our WMS colleagues Nicholas Bloom, Raffaella Sadun and John Van Reenen, we collected internal organizational data for over 3,000 firms in Africa and Latin America. The WMS is a unique dataset that includes levels of structured management practices and current governance data from over 10,000 manufacturing firms collected from 2004 to 2015 across 35 countries. To date, nearly 40% of these firms are owned by a founder or family member. The WMS methodology uses double-blind surveys to collect data on firms’ use of management practices and focuses on medium- and large-sized firms, selecting a sample of firms with employment of between 50 and 5,000 employees.¹⁷ The project is among a surge of emerging research on this subject, which has attempted to move beyond selective case studies and collect

¹⁵Likewise, if a firm was sold to another entity (person or another family), and that entity (the new owner or a family member of the new owner) holds the CEO position, the firm would also be classified under “family control”, though there were barely any instances of this case.

¹⁶In the current and future waves of the Ownership Survey we are also collecting data on the order of gender of the children.

¹⁷The WMS methodology was first described in Bloom & Van Reenen (2007). Survey instrument available at www.worldmanagementsurvey.org.

systematic and reliable data on this topic.

The WMS uses an interview-based evaluation tool, initially developed by an international consulting firm, that defines and scores from one (“little/no formal practices”) to five (“best practice”) a set of 18 basic management practices on a scoring grid. A high score represents a best practice in the sense that a firm that adopts the practice will, on average, increase their productivity. The combination of many of these indicators reflects "good formal structured management practices" as commonly understood, and our main measure of management practices in this paper represents the average of these 18 scores. The tool can be interpreted as measuring the level of formal managerial practices in three broad areas: operations & monitoring, target-setting and people management practices.

The survey seeks to unveil to what extent formal managerial structures are implemented in the firm, asking managers to describe their practices and evaluating them systematically on a set scale, rather than simply asking managers to name their management system or evaluate the quality of their practices themselves. Thus, the survey captures the degree of usage rather than the manager’s opinions and abstracts from possible mood influences of individual managers. Beyond the key measure of managerial structures at the plant level, the survey also collects a wealth of information on the firm, including firm location, size and current ownership information.¹⁸ A more thorough description of the WMS is provided in the Appendix.

2.3 Does management matter for family firms?

Our main aim in this paper is to explore whether the appointment of family versus non-family CEOs affects the quality of management in manufacturing firms, and why that might be the case. Establishing a causal relationship between quality of management and *productivity* is the subject of a parallel research agenda and is outside the scope of this paper. However, it is important for us to be able to put our results into context — namely considering how much “management matters” for firm productivity in emerging economies.

¹⁸Performance data is not collected at the time of the management survey, so researchers have to rely on external datasets and match them to the WMS data. The WMS data has been collected in waves over the past 10 years with cross-sections of firms in new countries added every wave as well as panel data for selected countries.

One hypothesis is that family firms might be different from other firms and not need management practices in the same way to be optimally productive. If this were the case, we would expect to find no significant relationship between management and firm outcomes in the sample of family firms. The best evidence to date on the topic is the [Bloom et al. \(2013\)](#) management experiment with family owned and controlled firms in India. They find that adopting a better set of management practices (in many ways parallel to those used in this paper) improved the treated firms' productivity by 17% in the first year. To supplement the experimental findings, we present evidence on the correlational relationship between management and firm performance in the context of the countries we are studying.

We find that management is significantly correlated with better firm outcomes for the sample of family firms. In this section we provide a brief analysis of this relationship for both the WMS Brazilian firms matched with the Brazilian industrial census and also the WMS firms that had available data in Bureau van Dijk's Orbis database, one of the most comprehensive databases of private and public firm information in the world. Although the Orbis coverage of Latin American countries is far from perfect, we hope that the results from a large Latin American economy such as Brazil will shed light on the expected relationship within the Latin American context. The reason we chose Brazil for this analysis is three-fold: 1) it is one of the countries for which we have the largest number of data points for ownership and firm organization (there are only four countries with approximately 1000+ data points: US, UK, India and Brazil); 2) it is a large and economically important country in a developing region and also has a large proportion of family firms (compared to the US/UK where only 20-30% of firms are founder or family owned); 3) the data both exists and is accessible.

To consider the relationship between family control and firm performance, we run a descriptive Cobb-Douglas specification:

$$y_{isc} = \beta_1 M_{isc} + \alpha_l l_{isc} + \alpha_k k_{isc} + \gamma' Q_{isc} + \Omega_s + \varphi_c + \varepsilon_{isc} \quad (1)$$

where y_{isc} is a measure of performance of firm i in industry s in country c (here, log of sales and log of value added).¹⁹ The conventional factor inputs we have data for are l (log of

¹⁹Sales for data for the non-Brazilian data comes from the Orbis database and is in US\$, while sales and value added are in BRL\$. Within each regression, the currencies are comparable. Because we use z-scores for the management index and logs for the outcome measures, however, units are less important in the

labour) and k (log of capital). Labour is measured as number of employees and capital is the firm’s capital stock in the measured year.²⁰ The coefficient of interest is β_1 , and M_{isc} is the main management measure. To build the management index we follow the conventional approach in this literature and first create z-scores for each of the 18 ordinal management practices, then take the average across them and again take the z-score of this sum to proxy for level of management. We refer to this variable as “z-management” in the tables.

Q_{isc} is a vector of other controls, including firm characteristics that might be correlated with output (firm age, a dummy variable for whether firm is publicly listed in the stock market, the proportion of workers with a college degree and average hours worked) and a set of survey noise controls (interviewer dummies, the seniority and company tenure of the manager interviewed, the day of the week and time of day the interview was conducted, the duration of the interview, and an indicator of the reliability of the information as coded by the interviewer). We also include industry and country fixed effects. We cluster the standard errors at the firm level.²¹

Table 1 reports the descriptive results. Columns (1) to (6) use the dataset of WMS Brazilian firms matched to the Brazilian annual industrial survey (*Pesquisa Industrial Anual - PIA*). PIA is an industrial census and yielded a match with the WMS firms of approximately 95%. PIA is a well-used and reliable dataset, with the only downside that all analyses must be done in their offices in Brazil to comply with microdata confidentiality restrictions. We used their measures of firm gross sales, value added and employment. Columns (7) to (9) use the best available sample from Orbis database that matches WMS firms, and primarily includes European countries where the reporting requirements are more stringent. We include it here mainly as a comparison group. We discuss each column in turn.

[Table 1 here]

Columns (1) and (4) show that the raw correlation between management and value added

interpretation of the results.

²⁰The Brazilian industrial census (PIA) does not collect a direct measure of capital, but the *Instituto de Pesquisa Econômica Avançada* (IPEA), a Brazilian economic research institute, has built a widely used set of four alternative measures of capital based on the data available from PIA. They kindly made these measures available to us, and we ran the specification iterating among the four. The results are robust to all four measures of capital and although the coefficients do not change much, we present the results with the ‘middle’ result rather than the strongest or weakest.

²¹Our unit of observation for the performance and management analysis is the establishment (plant) level, so we cluster at the firm level to take into account those companies which have multiple production sites in our dataset.

and sales respectively is strong and substantial. Once we control for labour, capital and a series of firm, industry and noise controls, the coefficients more than halve in size but remain substantial. The coefficient of z-management in Column (2), including only controls for capital and labour, suggests that a one standard deviation increase in management practices is associated with approximately 46% higher value added.²² For the full WMS sample, a standard deviation is 0.66 points. When we include the other series of controls in Column (3) the management coefficient is again about halved, but still significant, suggesting a conditional correlation of approximately 22% higher value added for a one-standard deviation increase in management quality. In terms of sales, we see a similar pattern. Column (6) suggests that a one standard deviation increase in management quality is associated with approximately 15% higher sales for Brazilian family firms. The relationship qualitatively holds for the Orbis sample in Columns (7), (8) and (9).

Although this is naturally only a conditional correlation, we take it along with Bloom et al. (2013) experiments as evidence that improving the quality of the management practices we measure here is likely to improve firm performance even in family firms. This should hopefully appease concerns that there is something happening within the organization of family firms in particular that makes such practices irrelevant, and serve as evidence against the argument that family firms “do not need” this type of management. Indeed, we suggest that poor management practices could be a channel that explains at least part of the poor performance of family firms vs. non-family firms documented elsewhere in the literature.

2.4 How different are family and non-family firms?

We find a correlation between management and firm productivity in the sub-sample of family firms, and Figure 2 in the introduction suggests one important factor could be the owner’s choice of CEO and the CEO’s family identity. The figure shows the distribution of quality of management for firms owned and run by families, firms owned by families but run by a professional CEO, and firms with non-family private ownership run by a professional CEO. It is clear that family owned firms that are *not family controlled* are just as well managed as those under other governance structures but also under professional management. The Kolmogorov-Smirnov test of equality of distributions suggests that the

²²Calculated as $(e^{0.379} - 1) \times 100$.

distribution of firms that are not family owned-and-controlled is not statistically different from the distribution of firms owned by families but controlled by a professional CEO. The test also suggests that both distributions are statistically different from the distribution of firms owned-and-controlled by a family.

But what is so different about family firms? This section will explore the observable differences between the family and non-family firms in the sample. Table 2 shows the difference in means across key characteristics of family versus non-family firms in our sample. As the literature suggests that the “family behind the family firm” drives important differences in firm governance, we turn first to the family characteristics of the CEO prior to succession.²³ We see evidence that the characteristics of the former CEO’s children in family vs. non-family firms are significantly different from each other. On average, former CEOs of firms that switched to non-family control are likely to have fewer children and likely to have fewer boys. Importantly, however, conditional on the first child being male, the average family size is not statistically different between the two groups. This will be relevant in our later discussion of instrument validity. Table A3 in the Appendix reports the summary statistics for the key dependent and independent variables in our empirical model in more detail.

[Table 2 here]

Turning to firm characteristics, we report the means and difference in means for the set of factors that have been shown to have a correlation with managerial structures, as in Bloom et al. (2014). Firms in the two groups are not significantly different from each other in terms of firm size, with means of 463 and 545 employees for family and non-family firms respectively, or firm age with means of 51 and 46 years respectively. In terms of the proportion of employees who have college degrees, non-family firms tend to have a slightly higher proportion, 14% for non-family firms versus 11% for family firms, though the difference in means is weakly significant. Over half of non-family firms are multinationals while only 12% of the family firms fall under the same category. Breaking down the manufacturing industries into high tech and low tech, we find that the share of family firms is higher in low tech industries than in high tech industries.

We also check the difference in means of a set of other firm organizational characteristics beyond those that are known in the literature to be correlated with management practices.

²³For example, Bertrand & Schoar (2006), Bertrand et al. (2008).

The means of firms in the family and non-family groups across several variables are not statistically different from each other, including a measure of span of control (number of direct reports to the plant manager), average hours worked per week by managers and number of production sites (at home and abroad). Non-family firms seem to be more hierarchical, with on average a larger number of levels between the CEO and the shopfloor — however, this statistic is not controlling for firm size. Finally, there is a difference in the average number of hours worked by non-managers, with workers in family firms working three quarter of an hour longer on average.

Lastly, considering the average scores across the management measure indices we see that family firms have significantly lower average scores compared to non-family firms overall, and across operations and monitoring and targets areas. Interestingly, people management does not seem to be statistically different in an unconditional difference of means test. We will return to these results in the next section.

3 Empirical results

3.1 Ownership structure and management: OLS results

Having discussed results on the relationship between firm performance and management for family firms, we now turn to exploring the relationship of family control and management. We first use the full WMS dataset and run the following OLS model, with results reported in Table 3:

$$M_{isc} = \alpha + \beta_1' \mathbf{Family}_{isc} + \beta_2' \mathbf{NonFamily}_{isc} + \theta' \mathbf{V}_i + \omega_s + \vartheta_c + u_{isc} \quad (2)$$

where M_{isc} is the z-scored management index for firm i in industry s in country c . \mathbf{Family}_{isc} and $\mathbf{NonFamily}_{isc}$ are vectors of dummy variables indicating five ownership and control categories broken down as follows: family firms are subdivided into “family owned, family CEO” and “founder owned, founder CEO,” while non-family firms are subdivided into “dispersed shareholders,” “privately owned, professional CEO” and “family owned, professional CEO.” The reference category is dispersed shareholders. \mathbf{V}_i is a vector of controls for firm i , including the log of the number of employees, log of firm age and a dummy variable for

multinational status. The survey noise controls are a set of interviewer dummies, manager’s tenure, day of week, survey wave year and interview duration. We also include country and industry fixed effects.

[Table 3 here]

Columns (1) through (3) use the full WMS sample, while columns (4) and (5) are restricted to only the countries that are also used in the main IV analysis in this paper, and Column (6) uses only the firms within these countries that are included in the IV specification. Column (1) shows the baseline relationship between the sub-categories and management excluding all controls, while Column (2) includes industry controls and Column (3) includes firm and noise controls. The industry controls only slightly reduce the coefficients, but firm and noise controls account for a more substantial share of the variation. The estimates in Column (3) suggest that the average family owned, family CEO firm has 0.289 standard deviations worse management than the average dispersed shareholder firm. The average founder owned, founder CEO firm has 0.320 standard deviations worse management than the average dispersed shareholder firm. We also observe that firms with professional CEOs, either family or privately owned, are also worse managed than dispersed shareholder firms (coefficients of -0.097 and -0.155, respectively) but better managed than firms with family CEOs. In Column (4) we restrict the sample to only countries included in our IV analysis and observe similar results to Column (3). The exception is that the coefficient on family owned, professional CEO firms is no longer significantly different from dispersed shareholder firms though this might simply be reflecting a noisier estimate as a result of the lower number of firms with this ownership and control type in the particular subset of countries we study.

Columns (5) further restricts the sample to exclude founder firms from the samples of all firms in the “IV countries,” and Column (6) shows results using only the sample of firms that are also used in the IV analysis. The purpose of this exercise is to show that the pattern of poor management practices in family owned, family CEO firms is persistent across several subsamples of the data. This negative and systematic relationship is not as clear for other types of ownership and control.²⁴ The coefficient in Column (6) suggests that

²⁴Although our identification strategy by design excludes founder firms, the coefficients on the relationship between founder-owned, founder CEO firms and management are not statistically different from that of family owned, family CEO firms and management. The similarity of the relationship between “first generation” family firms (founder owned, founder CEO) and “second generation onwards” family firms will

family-controlled firms in our analysis sample have, on average, 0.37 standard deviations worse management than dispersed shareholder firms. This is equivalent to about 56% of the standard deviation in the full management dataset.

We also check for the equality of the coefficients within and between the two broader categories of firms by conducting a Hausman test of the equality of coefficients and provide results at the bottom of the table. We first test the equality of the coefficients within each category of control, that is, a comparison of (i) family owned, family CEO and founder owned, founder CEO; and of (ii) family owned, professional CEO and privately owned, professional CEO, showing that for Column (3) we cannot reject the hypothesis that the coefficients are significantly different from each other within each category.²⁵ We also test for the equality of coefficients between the two broader categories, that is, testing whether family firms controlled by family CEOs and professional CEOs. We find that we can reject the null hypothesis that they are equal in specifications (1) to (5), and can nearly reject the null hypothesis in Column (6), despite the noisier data. This analysis suggests that the combination of several sub-categories into two major categories based on who *controls* the firm and not who *owns* the firm is reasonable for the purposes of this study.

3.2 Ownership structure and management: IV results

3.2.1 IV approach: exploiting conditional exogenous variation in gender composition of the outgoing CEO's children

We have established that family control across firms and countries is significantly correlated with management quality, but we cannot infer causality from a simple OLS model. There are several reasons why the OLS results could be biased. There could be omitted variable bias where there is some factor driving both CEO choice and management quality. If the firm is able to stay alive as a family controlled firm in a competitive environment, there is likely some positive productivity shock that both drives CEO choice and their choice of management practices. There could also be reverse causality, as it is possible that different control structures, say, less concentrated control, leads firms to have better management practices, but it is also possible that better management in turn allows firms to transition to

inform our discussion of external validity at the end of this paper.

²⁵Less crucially, we do see a difference between the excluded category of founder owned, founder CEO and family owned, family CEO for the countries in our IV sample.

control structures with, say, less concentration of control at the top. In short, it is difficult to pin down the real effect of family control on firm performance and organization from an OLS analysis. We expect there to be a positive bias in OLS, and that the true effect is significantly more negative.

In order to establish the true effect, we need to find a source of variation in family control that is exogenous to the level of managerial structures in a firm. One instrument that is particularly useful in determining family control is the family characteristics of the outgoing owner-CEO. In particular, we explore the gender composition of the children of the former owner-CEO as identifying variation. We use three main variations of this instrument: (a) a dummy variable for whether there was at least one son among the children, conditional on the number of children (b) the number of boys, conditional on number of children, and (c) a dummy variable for whether the first child was male. The rationale is that if the owner-CEO has a male child he is more likely to keep the firm under family control.²⁶ The gender of the first child instrument has been used by [Bennedsen et al. \(2007\)](#) with Danish data of family firms CEOs, for example.

By design, this IV strategy requires that at least one succession of power has taken place. More specifically, at the point where a family owner-CEO makes the decision to pass control of the firm to the next generation of family members, hire a professional CEO or sell the firm outright, we posit that this decision is heavily influenced by the gender composition of the CEO’s children. Essentially, we are comparing “stayers” with “switchers”. The “stayers” are firms that stay with combined ownership and control - that is, family owned firms with family CEOs.²⁷ The “switchers” are firms that were founded by a founder/founding family, but have since “switched” into separate ownership and control, that is, where the CEO is not related through family ties to the majority shareholders of the firm. We use the measure of quality of management of the firm to be contemporaneous with the CEO presiding during that time, and the information on the gender of the preceding CEO’s children as the identifying variation.

²⁶Here and throughout the paper we use the masculine pronoun because the vast majority of founder/family owners and CEOs in our sample are, in fact, male.

²⁷Because we need at least one “switch” to have happened, although we consider founder owned and controlled firms under the category of “combined” ownership and control they are not part of our IV strategy.

3.3 IV-2SLS results

The dependent variable of the first stage of our two stage least squares (2SLS) strategy is $FamilyCEO_i$, a dummy variable that takes a value of 1 when the firm is owned and controlled by a family and 0 when it is not. The first instrument, $HADSONS_i$ is a dummy variable that takes a value of 1 if the former owner-CEO had at least one son. The second instrument, $SONS_i$ is the number of sons the former owner-CEO had, entered as a step function. The third instrument, $FIRSTSON_i$, is a dummy variable that takes a value of 1 if the former owner-CEO had a male first child and 0 if not. \mathbf{X}_i is the vector of firm controls. The first stage equations are as follows:

$$FamilyCEO_i = \alpha_{fs} + \rho_h HADSONS_i + \vartheta children_i + \boldsymbol{\eta}' \mathbf{X}_i + \nu_i \quad (3)$$

$$FamilyCEO_i = \alpha_{fs} + \sum_{j=1}^3 \rho_j SONS_j + \vartheta children_i + \boldsymbol{\eta}' \mathbf{X}_i + \nu_i \quad (4)$$

$$FamilyCEO_i = \alpha_{fs} + \rho_f FIRSTSON_i + \boldsymbol{\eta}' \mathbf{X}_i + \nu_i \quad (5)$$

The second stage regression of the impact of family control on the quality of management is:

$$M_i = \alpha_{ss} + \beta_f \widehat{FamilyCEO}_i + \vartheta children_i + \boldsymbol{\phi}' \mathbf{X}_i + \epsilon_i \quad (6)$$

where M_i is a measure of managerial structures in the firm, $\widehat{FamilyCEO}_i$ is the predicted value from the first stage regression and \mathbf{X}_i is the set of firm-level controls. The coefficient of interest is β_f : the effect of family control on quality of management. Table 4 shows a summary of the OLS and IV results. Column (1) shows the OLS regressions using the same sample as in the main IV specification, using only the Ownership Survey data that can be matched to the World Management Survey and has full information on the instrumental variable. Column (2) shows the reduced form using the instrument from our preferred IV specification.

[Table 4 here]

The bottom panel of Table 4 shows the first stage results for the three main instruments we

use in Columns (3) to (5), and repeats the results for our preferred instrument in Columns (6) to (8). The first stage is essentially a linear probability model of the probability that the firm had a family control succession, conditional on the previous CEO having at least one son (Columns 3, 6-8) or the first child being male (Column 5).²⁸ Column (4) shows the first stage results for using the number of sons as the IV. In this specification the number of sons enters as a step function, with dummy variables for each number of sons.

Still focusing on the bottom panel, Column (3) of Table 4 suggests that, controlling for number of children, a firm is approximately 30 percentage points more likely to have a succession to a family CEO if the previous CEO had at least one son. The Kleibergen-Paap Wald F-statistic test for weak instruments is 21.58, well above the [Stock & Yogo \(2005\)](#) 10% maximal IV size critical value. This suggests that the largest relative bias of the 2SLS estimator relative to OLS for our preferred specification is 10%.²⁹

Column (4) shows the results of using the number of sons as an IV. The coefficients and significance levels are similar to those of the “had sons” IV in Column (3), predicting an approximate 30 percentage points likelihood of a firm staying in the family if there is exactly one son in the family, and similarly for higher numbers of sons. Because we have multiple instruments here we report the Sargan-Hansen test of over-identifying restrictions resulting Hansen’s J statistic (because of the clustered standard errors) and corresponding p-value. We cannot reject the joint null hypothesis that the instruments are valid. However, this specification seems to have weaker instruments than our preferred specification as suggested by the lower Kleibergen-Paap Wald F-statistic of ~ 7.6 .

In Column (5) we use the gender of the first child as the instrument. The coefficient suggests that having a male first child is associated with a 12.4 percentage points higher probability of the firm remaining under the control of a family CEO. Considering the weak instruments test, the Kleibergen-Paap statistic sits between the specifications in Columns (3) and (4) with a statistic of 11.37.

The top panel of Table 4 shows the second stage results, along with the OLS results and

²⁸As suggested by [Angrist & Pischke \(2009\)](#). We use Stata’s `ivreg2` command, by [Baum et al. \(2002\)](#) to estimate these regressions.

²⁹The Kleibergen-Paap Wald statistic ([Kleibergen \(2002\)](#), [Kleibergen & Paap \(2006\)](#)) is the heteroskedasticity-robust analogue to the first-stage F-statistic, and we report this value because we use clustered standard errors at the firm level. Although there are no critical values specifically for the K-P statistic, [Baum et al. \(2007\)](#) suggests that the [Stock & Yogo \(2005\)](#) critical values for the Cragg-Donald Wald F-statistic could be used and thus we report them here to facilitate comparison.

reduced form. Column (3) is our preferred specification and suggests that a succession to a family CEO leads to 0.808 standard deviations worse management practices, significant at the 5% level (p-value: 0.037). The coefficients of the different iterations of the IVs are very similar to each other, and not statistically different. The coefficient in Column (5) is not significant but the sign and magnitude of the coefficient are broadly consistent with that of our preferred specification, albeit imprecisely estimated.

When comparing the family control coefficient in Column (3) of Table 4 to the one we get in the equivalent OLS regression in Column (1), we cannot reject the hypothesis that they are significantly different from each other as the standard errors around the IV coefficient are rather large. However, the IV results give us some confidence that the effect is, in fact, negative and provides new evidence that the OLS has a positive bias here.

In Columns (6) to (8) we break down the WMS management score into its three main components, including operations & monitoring, target setting and people management. We see that the coefficients are broadly consistent with the overall management measure, suggesting the negative relationship between a family succession of control and management is not likely to be driven by any one particular sub-area of management, but rather is a more general effect.

3.3.1 Assessing instrument validity: instrument informativeness

Although the results from the first stage are economically meaningful and statistically significant, in this section we present further statistics supporting the informativeness of our choice of instruments. At a glance, it is clear that the strongest instrument we have is the dummy variable for whether the outgoing CEO had at least one son or not. The results suggest that having at least one son is associated with an approximately 30 percentage points higher chance of a family control succession. In the countries that we study, the gender of the *first child* is not as strong a predictor of family succession, with a male first child predicting only a 12.4 percentage points higher chance of family control.

Figure 3 breaks down the firm control succession by the number of sons of the former CEO. We have restricted the sample used in this graph to only those used in the IV analysis. Interestingly, even when there are no sons in the family, control tends to be passed to other male family members or to professional CEOs (either through external hires or firm sale)

rather than daughters.

[Figure 3 here]

3.3.2 Assessing instrument validity: exclusion restriction

The exclusion restriction would fail to hold if the gender of the CEO’s children was directly related to any part of our measure of quality of management. In terms of the IV specification using the gender of the first child, this is rather “purely” random since the countries we are including in the analysis do not have histories of selective abortion or infanticide.³⁰ In terms of the ‘number of sons’ or ‘at least one son’, it could be argued that perhaps more devoted CEOs continue having children until they have a son to pass the firm on to. The exclusion restriction would not hold if this devotion to the family firm led to systematically better management and also to a larger family with more sons. This is generally a problem when looking at the effect of family control on sales or profits - that is, outcomes that could be affected more directly by a CEO’s higher effort (ie. time spent) to leave a legacy to their children.

The fact that management is the key outcome variable of interest here partially mitigates this problem. Management is an outcome that simple CEO effort or sheer determination has a much less straightforward effect on, as drivers of better management are not as simple as spending more time at work. Bloom et al. (2013) note that one of the main reasons firm owners in their Indian experiment were not adopting good management practices was lack of information — they simply did not know that they were poorly managed or how to adopt these practices. Although it could be that more devoted CEOs also spend more time to increase their own levels of education — noted in Bloom et al. (2014) as one of the drivers of good management — this is likely to take some investment time and it is unclear it would yield large enough changes in the short run that would upset the validity of our IV.³¹ In short, even if the owner-CEO chose to have more children because they were keen to keep the firm in the family, it is less obvious that this also determines the quality of management practices they choose to adopt in the firm, thus making variations on the

³⁰Although it has been noted to us that studies have shown that there are other external factors that might affect the gender of children *in utero*, such as testosterone levels of the parents.

³¹See Bandiera et al. (2012) for evidence on CEO time use. New evidence in Lemos, (*mimeo*) suggests that the effect of quality and quantity of tertiary education on management is significant, but small.

gender composition of children a plausible set of instruments.

To consider this potential issue statistically, we could verify whether the probability of the last child being a boy is higher or lower across groups. As we lack the data to perform such a test at this time, we use an alternative method to check whether this is likely to be a problem. At a first instance, we have taken the data we have on the gender of the first child and number of children, and plotted the distribution of children (ie. family size) conditional on the first child being either a boy or a girl in Figure 4. The distributions are nearly identical, suggesting that selective family size is less of a concern.

[Figure 4 here]

3.4 Robustness checks

We have carried out a series of robustness checks of our main results. Table 5 reports the results for our specifications from Table 4 using two different sets of sampling weights in Columns (1) to (3) and (4) to (6), and the results for two different functional forms of the number of sons IV, in Columns (7) and (8). The sampling weights in the first set of columns were calculated within each country, while the second set were calculated for the full sample including country fixed effects. The results are qualitatively similar to those in the main results table. The two different functional forms of the IV that we are exploring as a robustness check are:

$$FamilyCEO_i = \alpha_{fs} + \sum_{j=2}^3 \rho_j SON_j + \vartheta_{1i} SON_1 + \vartheta_{2i} children_i + \boldsymbol{\eta}' \mathbf{X}_i + \nu_i \quad (7)$$

$$FamilyCEO_i = \alpha_{fs} + \sum_{j=1}^3 \rho_j SON_j + \sum_{j=1}^3 \vartheta_j children_j + \boldsymbol{\eta}' \mathbf{X}_i + \nu_i \quad (8)$$

In Column (7), we attempt to address the possible concern that number of sons is endogenous because families have multiple children until they “finally get a son.” Here we input the dummy variable for “exactly one son” as a *control* rather than an IV. The rationale for this is to test whether the result was being driven by a family having *the first boy* - that is,

we control for the “first boy effect,” by pulling it out of the IV set and adding it to the set of controls. Given that the second stage results are not statistically different, this serves as evidence that the effect is not wholly driven by having exactly one boy. Column (8) shows the number of sons IV controlling for family size (number of children) also as a step function - that is, including number of children dummies instead of the single variable. We lose efficiency by including an extra set of dummy variables, but the coefficients are not statistically different from the other two iterations of this IV.

[Table 5 here]

3.5 Possible mechanisms: a preliminary discussion

Although this first step was verifying that, indeed, there is evidence of a causal effect of family CEO on quality of management, the result begs the question of “why.” Here we discuss a set of key possible mechanisms that may be driving poor management in family firms inspired in the discussion in [Gibbons & Roberts \(2013\)](#): education, information, preferences and incentives.

In terms of *education*, [Bennedsen et al. \(2007\)](#) show that Danish family CEOs tend to be less well educated than non-family CEOs. They suggest that if the firm is to stay under family control, the outgoing CEO inherently has a limited talent pool constrained by family size and is thus less likely to find a talented CEO when compared to the broader market. Within Latin America, however, it could also be that family CEOs invest in their children to groom them to become the future leaders of the company and thus they are just as well educated as their broader market counterparts. One possible way to consider this mechanism would be to take advantage of new “big data” datasets, such as online CV repositories like LinkedIn, and match this data with the management and ownership data from our database. As we have the name of the companies and CEOs we may be able to find information on education and past employment experience for the CEOs and perhaps even other family members working in the company.

Another possible mechanism is *information*. [Bloom et al. \(2013\)](#) suggest that managers simply do not know that they are badly managed. The WMS collects some data that can help shed light on this mechanism: at the end of the management interview, the interviewer asks the only personal opinion question of the survey: “On a scale of 1 to 10 and excluding

yourself, how well managed do you think the rest of your firm is?” The answer is then re-scaled to match the 1 to 5 scale of the WMS and the difference between the manager’s perception and the “true” WMS score become the average information gap variable. We show in Figure 5 that managers in family firms seem to be systematically less aware of their own shortcomings than those in non-family firms. Thus, it seems plausible that family firms are perhaps less well informed about (a) their own level of quality of management, (b) what “best practice” management is, (c) whether it is profitable for them to implement new practices, and (d) how to implement such practices in their firm even if they wanted to do so.

[Figure 5 here]

Finally, it could also be that *incentives*, or “influence costs,” are one of the mechanisms driving lower adoption of management. This mechanism works from the “bottom up” rather than “top down,” and the idea is that employees may accept new managerial structures (such as, say, increased monitoring of their work) from a new professional CEO, but would resist it from a family CEO who might be known to them. On the theoretical side, work by Meyer et al. (1992) suggests this is a plausible scenario, and there is also empirical evidence of such cases. Atkin et al. (2015), in their technology adoption experiment with soccer ball factories in Pakistan, show evidence that worker pushback is indeed a possible reason for lack of technology adoption. If we consider management as technology, as in Bloom, Sadun & Van Reenen (2015), this could be a mechanism driving the lower adoption of management practices in family firms.

It is conceivable that family firms may face a different set of costs when dealing with employees, and if there is a perception that modern management practices are inherently labour-saving, there might be resistance to adopting them. The next draft of this paper will include a theoretical framework considering this hypothesis.

4 Conclusion

We set out to investigate the effect of family control on firm organization and performance. We define family firms as firms that have a combined ownership and control structure - that is, firms where the same entity (or, family) both holds the majority of voting shares and the CEO position in the firm. Adding to previous work in this area, we find that

simple family *ownership* does not fully explain family firms' underperformance, but rather it is the effect of the combination of ownership and control that seems to be driving this. Given the notorious lack of data for private and family firms, particularly for emerging economies, we first collect a rich new dataset on the history of ownership and control successions for a sample of firms in Latin America and Southern Europe, and match it with a unique dataset on firm organizational structure and managerial practices. Relying on the body of work that has provided evidence on the strong relationship between managerial practices and firm performance along with our new evidence from Brazil, we suggest that poor management could be a channel driving family firms' poor performance. We consider whether the decision to appoint a family CEO had a causal effect on firm management, and provide a brief discussion on possible mechanisms.

The new dataset we collected allowed us to add to the correlational findings of [Bloom & Van Reenen \(2007, 2010\)](#) and suggest a causal relationship by using an instrumental variables approach. We explored the gender of the outgoing CEO's children as exogenous variation to identify the effect of a family CEO on the quality of management of a firm. We find convincing evidence that the gender mix of the children does affect the likelihood of a succession to a family CEO: in families where there is at least one male child the likelihood of a family succession of control is 30 percentage points higher. We also present descriptive evidence that this is, indeed, a stylized fact and strengthens our claim of the informativeness of the instrument. We argue that, conditional on number of children, the *gender mix* of the children is as good as random and unrelated to the managerial structures implemented in the firm, thus satisfying the exclusion restriction.

Our OLS and IV-2SLS results suggest that there is a statistically significant negative effect of family control, and the true effect sits somewhere between -0.369 (OLS result) and -0.808 (IV result). To put this in context, a one standard deviation change in management quality is associated with approximately 20% higher value added per employee in Brazilian family firms. If we take this proportional relationship, our results suggest that keeping the firm under family control leads to between 7% and 16% lower value added per employee in the average family firm.³² This result is strikingly within the same range as the main results from [Bennedsen et al. \(2007\)](#) in Denmark.

We believe that better management leads to better firm productivity, and thus we believe

³²Calculated as $0.369 \times 20\% \approx 7\%$; $0.808 \times 20\% \approx 16\%$

that our results have key implications for policies in emerging economies, where family firms dominate various industries. To the best of our knowledge, this is the first piece of work to show causal evidence of this negative effect of family control on *internal organization of the firm*, and also the first such analysis to be done with emerging economies. This is also, however, only the first step in this research agenda. Future research is needed into the mechanism behind the choice of family CEOs to implement less managerial structures than non-family CEOs, and what effect this might have on other firm outcomes and characteristics, such as on employee satisfaction, wages and work-life balance.

* p < 0.1, ** p < 0.05, *** p < 0.01. Standard errors in parentheses.

Note: All columns estimated by OLS with standard errors clustered by firm. Firm value added, capital measures and industry codes come from the Brazilian Industrial Survey (PIA) and Bureau van Dijk's Orbis dataset. PIA's values for sales, value added, employment and capital measures were averaged over 3 years around the year for when the management data was collected. z-management is the plant-level standardized management score. General controls include firm-level controls for average hours worked and the proportion of employees with college degrees (from the survey), plus a set of country dummies. Noise controls include a set of interviewer dummies, the seniority and tenure of the manager who responded, the day of the week the interview was conducted, the time of day the interview was conducted and the duration of the interview.

Columns (7) and (8) are unweighted.

Appendices

A Appendix

A.1 Ownership categories and additional summary statistics

Table A1 describes the definition of ownership and control structures used in this paper. We differentiate between *combined* ownership and control, which we refer to generally as “family firms” (for ease of exposition) and *separate* ownership and control “non-family firms.” Table A3 shows the summary statistics of the dataset we use in our analysis.

Table A1: Data categories - The Ownership Survey

Ownership category	Ownership & control	
	Non-family	Family
Founder or family owned		
<i>Founder owned, founder CEO</i>		✓
<i>Founder owned, professional CEO</i>	✓	
<i>Family owned, family CEO</i>		✓
<i>Family owned, professional CEO</i>	✓	
Privately owned (non-founding family owners)*		
<i>Single owner, owner CEO</i>		✓
<i>Single owner, professional CEO</i>	✓	
<i>Many owners, owner CEO</i>		✓
<i>Many owners, professional CEO</i>	✓	
<i>Dispersed shareholders**</i>	✓	

* For the category of Privately owned, at least one entity owns more than 25% of voting shares, and they are not members of the founding family.

** For the category of Dispersed shareholders, no one entity owns more than 25% of voting shares.

Figure 6 shows the share of employment attributed to family firms in the WMS dataset. This graph is to quell concerns that, while there are many firms in the manufacturing sector in these countries, they account for a small share of employment.

Table A2: IV sample: countries

Country	Sample size	Percentage of total

A.2 Management across regions and industries

One important consideration is to what extent we should be treating this relationship between family control and management practices as something that is common across countries. It could be that family ownership and control matters more in countries where there is less competition, better rule of law, or a different mix of industries. To consider this, we broke the full WMS sample into the continental regions and report the results in Table A4. The coefficients across nearly all regional specifications are not statistically different from each other, with the exception of Africa. This suggests that across the world, being owned and controlled by a founder or founding family is associated with a similar negative effect on firm management.

Table A4: Management and family ownership and control across regions, WMS

	Anglo-Saxon	Sca' via & W. Europe	S & C Europe	Latin America	Asia	Africa
Family Control = 1	-0.166*** (0.024)	-0.149*** (0.032)	-0.162*** (0.030)	-0.211*** (0.021)	-0.168*** (0.029)	-0.122*** (0.034)
Ln(employment)	0.123*** (0.008)	0.153*** (0.012)	0.178*** (0.017)	0.221*** (0.010)	0.129*** (0.010)	0.134*** (0.016)
Observations	4299	2438	1904	3049	2453	867
Noise controls	✓	✓	✓	✓	✓	✓
Industry controls	✓	✓	✓	✓	✓	✓
Firm controls	✓	✓	✓	✓	✓	✓

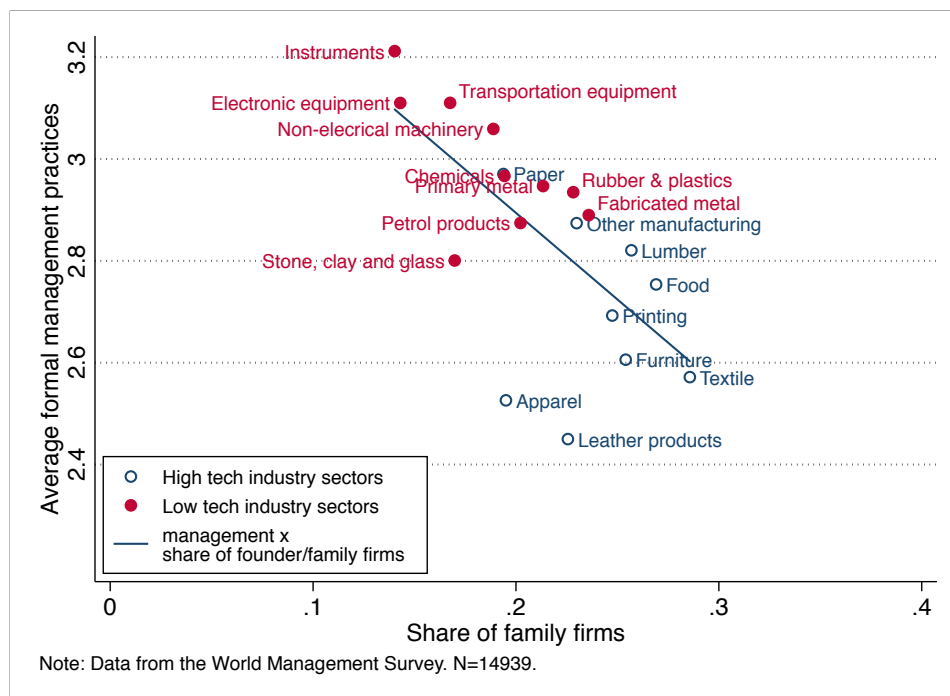

* p < 0.1, ** p < 0.05, *** p < 0.01. Standard errors in parentheses.

Note: All columns estimated by OLS with standard errors clustered by firm and reported in brackets below the estimates. Sample includes all firms with controls data. Management is the plant-level management score. Controls include a full set of country dummies, US-SIC dummies and year dummies, as well as firm-level controls including the proportion of employees with college degrees (from the survey), interviewer dummies, the seniority and tenure of the manager who responded, the day of the week the interview was conducted, the duration of the interview, and an indicator of the reliability of the information as coded by the interviewer.

Finally, another interesting feature to consider in terms of firm characteristics is the industrial mix in each group of firms. Figure 7 shows the relationship between management and the share of family firms within each 2-digit industrial sector. Each observation is an industrial sector and it is colour coded to indicate high (red) and low (hollow blue) tech industries. High tech industries are overwhelmingly both better managed and have lower shares of family firms. This result echoes one of the findings in [Bennedsen et al. \(2007\)](#),

where they suggest that the negative effect of family CEOs are worse for firms in higher tech industries. To take this into account we ensure we add industry fixed effects to all our specifications, and this is an avenue of research that could be explored in the future with more detailed administrative datasets.

Figure 7: Share of family firms and average management scores, by industry

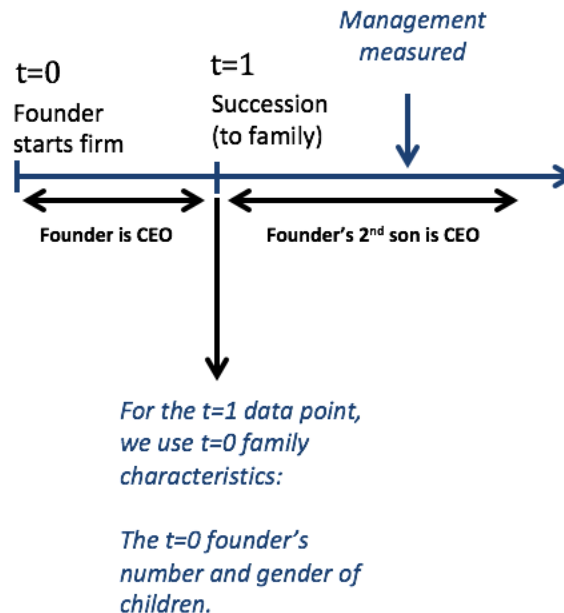

A.3 Ownership survey: data structure details

Figure 8 shows a diagram of a hypothetical firm surveyed both by the Ownership Survey and the WMS. In this example, the WMS surveyed this hypothetical firm once between $t = 1$ and $t = 2$. The Ownership Survey collected data on: the date of foundation ($t = 0$) and each date of succession ($t = 1$); who owned the firm at each time bracket and the family characteristics of the founder and each family owner-CEO after. In terms of the merged data, the family characteristics of the founder, who owned and managed the firm between $t = 0$ and $t = 1$, will be the instrumental variables for the WMS management measurement after $t = 1$.

For example, take two hypothetical Brazilian firms: Firm A is currently a “family firm” and Firm B is currently a “non-family firm.” Firm A was founded in 1980 and its founder handed down control of the firm to his son in 2005, who is still presiding over the company. Firm B was founded in 1990 by a founder who decided to sell the firm in 2000 to a set of investors (“private individuals,” by our categorization). These investors chose to hire a professional CEO to lead the firm. The firm today is still owned by these investors and the CEO continues to be the same professional hired in 2000. As the first WMS wave for Brazil was in 2008, we have a snapshot measure of the quality of management in both firms during the tenure of the founder’s son for Firm A and during the tenure of the professional CEO in Firm B. We do not have measures for either of the founders’ tenures in the earlier decades of these firms and thus cannot use panel data methods with the current dataset. The Ownership Survey collected information on the family characteristics of the founders of both firms and enables us to then use the gender composition of the founders’ children as an instrument for the founders’ choice of succession into another generation of a family firm or out of family control. Most of our data at the moment only has one management data point and complete data on the ownership background.

Figure 8: Hypothetical example

A.4 Ownership Survey: A brief illustration using the early days of the Ford Motor Company

Beyond understanding how our data is matched to the WMS, a crucial definition worth reiterating is that when we use the term *family firm* we mean family control of the firm in terms of the same family entity owning the majority of the voting shares of the firm *as well as* having a family member presiding over the company as CEO: *combined* ownership and control. To illustrate the data we collected and our definitions, it is useful to consider a well-known example such as the early days of the Ford Motor Company. Ford was founded in 1903 by Henry Ford, who had one son. In 1919 Henry Ford passed the position of CEO to his son, Edsel, until Edsel (unexpectedly) died in 1943. Edsel had four children: three boys and one girl. Henry Ford briefly took control for the interim two years until 1945 when Edsel's first son, Henry Ford II, returned to the US and assumed the helm of the firm. Henry Ford II had three children: two girls and one boy, Edsel Ford II.³³ In 1956, Ford went public in the largest IPO (initial public offering) of common stock shares in history at the time, but the Ford family still retained 40% of the voting shares.³⁴ Up to this point, the Ford Motor Co. would be considered a *family firm* in the Ownership Survey as the Ford family held over 25% of the voting shares and a family member from the original founding family held the CEO position in the firm. We would have, thus far, registered three successions of power within the family.³⁵

A *non-family firm*, on the other hand, has *separate* ownership and control. Continuing with the Ford Motor Co. example, in 1980 Phillip Caldwell became the first non-Ford-family member to take the post of CEO. From 1980 onwards Ford is considered a *non-family firm* in our analysis. The data point would be recorded as “family owned, professional CEO,” (ie. the green boxes in Figure 1) but as discussed earlier, we combine all categories that are not owned and controlled by families under *non-family firm*. An example of what the early Ford history would look like in our survey instrument is shown in Figure ???. If the Ford family ever chose to divest or dilute their voting shares such that the family's voting ownership stake of the firm fell to below 25% of the shares, they would then continue to

³³Edsel Ford II ran Ford Australia between 1978 and 1980.

³⁴According to Ford Motor Co.'s website. It is important to note that when they took the company public the family separated the type of stock offered into 95% Class A shares (no voting rights) and 5% Class B (voting rights) shares. The Ford family in fact owned less than 2% of the company as a whole, but crucially, they own 40% of the *Class B voting shares*, affording them majority control of the company.

³⁵Henry Ford 1903-1919, Edsel Ford 1919-1943, Henry Ford 1943-1945, Henry Ford II 1945-1979.

be coded as a *non-family firm* category, but their ownership sub-category would change to *dispersed shareholders*.³⁶ Crucially, our identification strategy would not use ownership successions that, for example, started as “family owned, professional CEO” and switched to “dispersed shareholders, professional CEO.” Our identification is coming from firms that have successions of *control*, such as a “family owned, family CEO” firm hiring a professional CEO or, alternatively, selling the firm outright/diluting their shares to under 25% voting ownership to non-family investors who then hire a professional CEO.

A concern could be that what we will capture with this strategy is the effect of the change in ownership rather than the change in control, as in our analysis we combine firms that have changed *only control* with those who change *ownership and control*. The best scenario would, indeed, be to have a large sample of firms that switched from having family ownership and control to family ownership and professional control, but that is a limitation of our dataset (indeed, of “reality”) that we do not think is fatal. First, as evidenced in Figure 1, although the family ownership with professional CEO structure is relatively more common in OECD countries than in middle- and low-income countries, it still constitutes a very small share of the overall ownership and control structures that we study. Among the countries we study it is an even smaller part of the share of firms in the economy. Thus, the next best alternative is comparing family owned and controlled firms with non-family owned and professionally controlled firms.³⁷

³⁶History of the Ford Motor Co. primarily obtained from the Ford Motor Co.’s website: <https://corporate.ford.com/company/history.html>, last accessed on January 15, 2016.

³⁷Once we match the Ownership Survey data with the Brazilian industrial census we will hopefully be able to say more about the effect of changes in ownership without changes in CEO.

-44 = doesn't know/information not available

DEFINITIONS:

**** Dispersed Shareholders - No single entity (person, family or company) owns more than 25.01% of the shares, i.e. no entity owns a controlling stake. This category does not include Cooperatives or Management types of GUO.

IF ONE SINGLE ENTITY OWNS MORE THAN 25.01%, THEN:

**** Family/ Founder owned - The company founder or founding family still owns the company.

**** Government - The company is majority owned by a government or state enterprise. This can be of the same nationality as the company or a foreign one.

**** Joint Venture - Two entities founded the company and each owns 50% of the shares. For India and China only: Two entities founded the company and both own at least 25% of the shares.

**** Managers - The company managers and executives own the controlling stake. This is not to be confused with cooperative/employee ownership and private individuals.

**** Private Individuals (non-family) - One or more private individuals own a controlling stake and they are not the founders or heirs to the founders of the company AND are NOT blood-related

**** Private Individuals (family) - One or more private individuals own a controlling stake and they are not the founders or heirs to the founders of the company AND are blood-related. For example, this applies to companies that have been acquired by a family or other individuals from a previous owner or the founding entity. **** Private Equity or Venture Capital - A private equity, venture capital or investment fund type of enterprise owns the company after acquisition and usually for restructuring purposes. If the PE/VC company were owned by a Bank or private individuals or other entity, the ownership would still be defined as PE or VC.

F = female
M = male
-99 = refused
-44 = doesn't know/information not available

A.5 World management survey

One of the binding constraints for growth and development in emerging economies and low income countries is a lack of capital, both tangible and intangible. Investments in tangible capital such as better machines or other hard technology are relatively straightforward and often enacted by governments because of their greater visibility and ease of procurement, but there are large costs associated with such tangible capital upgrading programs. Investment in intangible capital such as organizational capital (ie. management practices) can often yield similar returns with lower levels of investment. For example, substantial improvements to organizational practices in firms can yield a return that could be comparable to increasing the workforce by 15% or capital by 40%.³⁸ In education, a one standard deviation improvement in the quality of management in a school is associated with better student outcomes in year-end exams to the order of 0.2-0.4 standard deviations.³⁹

The idea that *management matters* dates at least as far back as 1887, when Francis Walker wrote the following in the first volume of the Quarterly Journal of Economics: “It is on account of the wide range [of management quality] among the employers of labor, in the matter of ability to meet these exacting conditions of business success, that we have the phenomenon [...] of some employers realizing no profits at all, while others are making fair profits.”

Since then, a large literature has developed around the idea of management and productivity, and universities have even launched a whole new set of professional schools focused on producing graduates of business administration. Empirical evidence on management practices, however, had been generally presented in the form of case studies, until Bloom & Van Reenen (2007) pioneered the use of a new survey tool to systematically measure the quality of management in manufacturing firms across countries. This new research finds that large variations in the quality of management across firms and countries are also strongly associated with differences in performance. For example, better managed firms tend to have significantly higher productivity, higher profitability, faster growth, higher market value (for quoted firms) and higher survival rates (see Bloom et al. (2014) for a survey).

The WMS is a unique dataset that measures the quality of management practices of firms

³⁸World Management Survey team (n.d.)

³⁹Bloom, Lemos, Sadun & Reenen (2015)

via over 15,000 one-hour, structured phone interviews with plant managers. The data currently spans waves between 2002 to 2014, and includes 35 countries. The management survey methodology, first described in Bloom & Van Reenen (2007), uses double-blind surveys to collect data on firms' use of operations management, performance monitoring, target setting and talent management in their day-to-day runnings. The WMS focuses on medium- and large-sized firms, selecting a sample of firms with employment between 50 and 5,000 workers. The project is among a significant surge of emerging research on this subject, which has attempted to move beyond selective case studies and collect systematic and reliable data to empirically test management theories.

To measure management practices, the WMS uses an interview evaluation tool based on the questionnaire McKinsey & Co. uses in their baseline client evaluations. The tool was then adapted for research purposes and enhanced to include insights from the management literature that would be important for researchers to measure. For example, the WMS tool measures practices similar to those emphasized as relevant in earlier work in the management literature, by for example Ichniowski et al. (1997) and Black & Lynch (2001). The tool was piloted in 2002 and further refined, and since the first major wave in 2004 it has remained largely the same. The tool defines a set of 18 basic management practices and scores each practice on a scale from one ("worst practice") to five ("best practice") on a scoring grid.⁴⁰ A high score represents a best practice in the sense that firms adopting the practice will, on average, see an increase in their productivity. The combination of many of these indicators reflects "good management" as commonly understood, and the main measure of management practices represents the average of these 18 scores.

Conceptually, the scores suggest a gradual increase in formalization and usage of the management practices being followed. A score of 1 indicates little to no formal processes in place, and suggests the firm deals with day to day activities in a very ad-hoc manner. A score of 2 suggests that there are some informal processes in place, though they are enacted by the acting manager and not part of the "official" day to day running of the firm. If the manager was not in the plant for any reason, the practices would not be followed. A score of 3 indicates that a firm has some formalized management processes in place, though they have some weaknesses such as the process is not regularly reviewed or it is not often used properly. If the manager was away, however, the process could be picked up by a stand-in manager as it would be known as "normal running" of the firm by most staff. A

⁴⁰The full instrument is available at www.worldmanagementsurvey.org

score of 4 suggests that firms have good and flexible processes in place, that are routinely reviewed and are well-known to at least all managers in the firm. A score of 5 suggests that the firm not only has “best-practice” processes in place, but that these processes are deeply embedded in the corporate culture and have substantial employee buy-in, from the shopfloor, through middle management and up to the C-suite. It is considered that firms scoring under 2 are very badly managed firms, and those scoring over 4 are well-managed firms.

The survey measures management practices in three broad areas:

1. *Operations management & performance monitoring practices*: testing how well lean (modern) manufacturing management techniques have been introduced, what the motivation and impetus behind changes were, whether processes and attitudes towards continuous improvement exist and lessons are captured and documented, whether performance is regularly tracked with useful metrics, reviewed with appropriate frequency and quality, and communicated to staff, and whether different levels of performance lead to different process-based consequences.
2. *Target setting practices*: testing whether targets cover a sufficiently broad set of metrics, including short and long-term financial and non-financial targets, and whether these targets are based on solid rationale, are appropriately difficult to achieve, are tied to the firm’s objectives, are well cascaded down the organization, are easily understandable and are openly communicated to staff.
3. *Talent management practices*: testing what emphasis is put on overall talent management within the firm and what the employee value proposition is, whether there is a systematic approach to identifying good and bad performers and rewarding them proportionately or dealing with bad performers.

Crucially, this methodology is uniquely useful because the types of questions asked ensure the survey is capturing how management practices are implemented in the firm, rather than how the managers feel or what their opinions are about management. The survey questions ask managers to describe their practices including several examples, and the interviewer independently evaluates the responses systematically on a pre-set scale. Thus, the WMS captures the degree of usage rather than the superficial adoption of these practices and abstracts from possible mood influences of individual managers. Beyond the key measure of management practices at the plant level, the WMS also collects a wealth of information

on the firm, including firm location, size and ownership structure.

The management data has been collected in waves over 12 years with cross-section of firms in new countries added every wave as well as panel data for selected countries. The US, UK, France, Germany, Italy and Greece were surveyed in 2004, 2006, 2010 and 2014. China, Japan, Poland, Portugal, and Sweden were surveyed in 2006 and 2010. India was surveyed in 2006, 2008 and 2010. Brazil was surveyed in 2008 and 2013. Canada and Ireland were surveyed in 2008. Australia and New Zealand were surveyed in 2009. Chile was surveyed in 2009 and 2013. Argentina and Mexico were surveyed in 2010 and 2013. Singapore was surveyed in 2012. Colombia, Ethiopia, Ghana, Kenya, Mozambique, Nicaragua, Nigeria, Spain, Tanzania, Turkey and Zambia were surveyed in 2013. Myanmar, Vietnam were surveyed in 2014.

Figure 9: Developing countries rank lowest in quality of management

One of the key stylized facts emerging from the WMS data is that firms in developing countries have much worse management practices than firms in developed countries. Figure 9 shows all countries in the WMS sample ranked by the average quality of management in the

country. The ranking is surprisingly stable even after controlling for firm size, suggesting it is not simply a matter of rich countries having larger firms that are better managed. It is immediately clear that developing countries are at the bottom of the rank, with only the middle-income economies of Mexico and Chile placing among the top half of the country ranking.

Figure 10: There is wide variation of management quality within countries

Beyond a wide distribution of scores across countries, the data also shows that there is a substantial amount of variation within countries as well. In fact, [Bloom et al. \(2014\)](#) suggest that the low average quality of management in developing countries appears to be attributed to a large tail of badly managed firms coexisting with firms boasting world-class management practices. Figure 10 depicts this point, showing the distribution of the management measure across countries. The vertical line marks where the score of 2 is in each sub-graph, and it is immediately clear that in the lower-ranked countries such as, for example, India or Brazil, the mass of firms with a score under 2 is much larger than in countries higher up in the ranking such as the US, Germany or Great Britain. In Latin America and Asia, 15% of firms fall in this range while in Africa the share is just under

30%. In contrast, the share of firms scoring under 2 is only 2% in North America and 8% in Europe. Taking a closer look at the characteristics of firms populating the lower tail of the distribution yields a striking observation: 75% of the firms in Latin America and Asia in this range are family firms. The share is 60% in Africa, 35% in North America and 50% in Europe.

A.6 WMS topics

Practices	What is the WMS measuring
Operations Management and Performance Monitoring	
Introducing Lean (modern) Techniques	Measures how well lean (modern) manufacturing management techniques have been introduced
Rationale for introducing Lean (modern) Techniques	Measures the motivation/impetus behind changes to the operational processes, and whether a change story was well communicated turning into company culture
Continuous Improvement	Measures attitudes towards process documentation and continuous improvement
Performance Tracking	Measures whether firm performance is measured with the right methods and frequency
Performance Review	Measures whether performance is reviewed with appropriate frequency and follow-up
Performance Dialogue	Measures the quality of review conversations
Consequence Management	Measures whether differing levels of firm performance (not personal but plan/process based) lead to different consequences

Target Setting	
Target Balance	Measures whether targets cover a sufficiently broad set of metrics and whether financial and non-financial targets are balanced
Target Interconnection	Measures whether targets are tied to the organization's objectives and how well they cascade down the organization
Time Horizon of Targets	Measures whether the firm has a '3 horizons' approach to planning and targets
Target Stretch	Measures whether targets based on a solid rationale and are appropriately difficult to achieve
Clarity and Comparability of Targets	Measures how easily understandable performance measures are and whether performance is openly communicated to staff

People Management	
Managing Talent	Measures what emphasis is out on overall talent management within the organization
Rewarding High Performers	Measures whether there is a systematic approach to identifying good and bad performers and rewarding them proportionately
Removing Poor Performers	Measures how well the organization is able to deal with underperformers
Promoting High Performers	Measures whether promotion is performance-based and whether talent is developed within the organization
Retaining Talent	Measures whether the organization will go out of its way to keep its top talent
Creating a Distinctive Employee Value Proposition	Measures the strength of the employee value proposition
